### §1.1 Simple Linear Regression Models

Consider

$$Y_i = \mu + \varepsilon_i$$

with  $\varepsilon_i \overset{\text{i.i.d}}{\sim} N(0, \sigma)$ ; specifically,  $Y_1, \ldots, Y_n \overset{\text{i.i.d}}{\sim} N(\mu, \sigma)$ . We want to estimate  $\mu$  and  $\sigma^2$  using least squares or method of maximum likelihood (MML).

Method of Least Squares (OLS – Ordinary Least Squares):

$$\min Q = \sum_{i=1}^{n} (Y_i - \mu)^2$$

$$\frac{\partial Q}{\partial \mu} = -2 \sum_{i=1}^{n} (Y_i - \mu) = 0$$

$$\sum_{i=1}^{n} Y_i - n\hat{\mu} = 0$$

$$\implies \hat{\mu} = \overline{Y}$$

Method of Maximum Likelihood (MML):

$$f(y_i) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{1}{2\sigma^2}(y_i - \mu)^2}$$

$$= (2\pi\sigma^2)^{-\frac{1}{2}} e^{-\frac{1}{2\sigma^2}(y_i - \mu)^2}$$

$$L = f(y_1) \dots f(y_n) = (2\pi\sigma^2)^{-\frac{n}{2}} e^{-\frac{1}{2\sigma^2}\sum (y_i - \mu)^2}$$

$$\ln L = -\frac{n}{2} \ln 2\pi\sigma^2 - \frac{1}{2\sigma^2} \sum (y_i - \mu)^2$$

$$\frac{\partial \ln L}{\partial \mu} = 0, \qquad \frac{\partial \ln L}{\partial \sigma^2} = 0$$

Solve the above, we obtain the MLE of  $\mu$  and  $\sigma^2$ 

$$\hat{\mu} = \hat{y}, \qquad \hat{\sigma}^2 = \frac{\sum (y_i - \hat{\mu})^2}{n} = \frac{\sum (y_i - \overline{y})^2}{n}$$

Notice that  $\hat{\sigma}^2$  is biased and we adjust it to be unbiased as follows

$$S^2 = \frac{\sum (y_i - \overline{y})^2}{n - 1}$$

#### §1.2 Prediction Problem

Given  $Y_1, \ldots, Y_n$ , we want to predict a new Y, e.g.,  $Y_0$ . An educated guess here is

$$\hat{Y}_0 = \overline{Y}$$

- 1. Predictor assumption:  $\hat{Y}_0 = \sum_{i=1}^n a_i Y_i$
- 2. We want  $\hat{Y}_0$  to be unbiased, i.e.,  $E\hat{Y}_0 = \mu$

$$E \sum a_i Y_i = \mu$$
$$\sum a_i E Y_i = \mu$$
$$\implies \sum a_i = 1$$

3. Minimize the mean square error of prediction, i.e.,

$$E\left(Y_0 - \hat{Y}_0\right)^2$$
 s.t.  $\sum a_i = 1$ 

Notice that this is a constraint optimization problem, we use the method of Lagrange multiplier to obtain

$$\min Q = E\left(Y_0 - \hat{Y}_0\right)^2 - 2\lambda \left(\sum a_i - 1\right)$$

Note:  $EW^2 = var(W) + (EW)^2$ 

$$\min Q = \operatorname{var}\left(Y_0 - \hat{Y}_0\right) - 2\lambda \left[\sum a_i - 1\right]$$

$$= \operatorname{var}(Y_0) + \operatorname{var}(\hat{Y}_0) - 2\operatorname{cov}\left(Y_0, \hat{Y}_0\right) - 2\lambda \left[\sum a_i - 1\right]$$

$$= \sigma^2 + \sigma^2 \sum a_i^2 - 2\lambda \left[\sum a_i - 1\right]$$

$$\frac{\partial Q}{\partial a_i} = 2\sigma^2 a_i - 2\lambda = 0$$

$$a_i = \frac{\lambda}{\sigma^2}$$

Notice that  $a_1 = a_2 = \ldots = a_n = \frac{\lambda}{\sigma^2}$ . So

$$\sum a_i = \frac{n\lambda}{\sigma^2} = 1 \implies \lambda = \frac{\sigma^2}{n}$$

Thus, we can see that

$$a_i = \frac{1}{n}$$

and therefore since  $\hat{Y}_0 = \sum a_i Y_i$ , it follows that  $\hat{Y}_0 = \overline{Y}$ .

Prediction Interval:

$$Y_0 - \hat{Y}_0 \sim N\left(0, \sigma\sqrt{1 + \frac{1}{n}}\right)$$

Recall from 100B

$$\frac{(n-1)S^2}{\sigma^2} \sim \mathcal{X}_{n-1}^2$$

So,

$$\frac{\frac{Y_0 - \hat{Y}_0 - 0}{\sigma \sqrt{1 + \frac{1}{n}}}}{\sqrt{\frac{(n-1)S^2}{\sigma^2}/(n-1)}} = \frac{Y_0 - \hat{Y}_0}{S\sqrt{1 + \frac{1}{n}}} \sim t_{n-1}$$

We can now construct the prediction interval for  $Y_0$  as follows

$$P\left(-t_{\frac{\alpha}{2};n-1} \le \frac{Y_0 - \hat{Y}_0}{S\sqrt{1 + \frac{1}{n}}} \le t_{\frac{\alpha}{2};n-1}\right) = 1 - \alpha$$

Finally,  $Y_0 \in \hat{Y}_0 \pm t_{\frac{\alpha}{2};n-1} S \sqrt{1 + \frac{1}{n}}$ .

**Remark 1.1.** Compare this to the confidence interval for  $\mu: \ \mu \in \overline{Y} \pm t_{\frac{\alpha}{2};n-1} \frac{S}{\sqrt{n}}$ .

# $\S2$ Lec 2: Sep 29, 2021

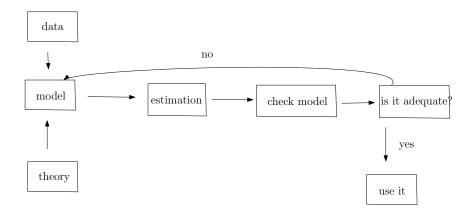

# §2.1 Linear Regression

Consider a simple regression model

$$Y_i = \beta_0 + \beta_1 X_i + \varepsilon_i$$
 or  $Y_i = \beta_1 X_i + \varepsilon_i$ 

Data:

$$\begin{array}{c|cc} y & x \\ \hline y_1 & x_1 \\ \vdots & \vdots \\ y_n & x_n \end{array}$$

where the parameters are

$$\begin{cases} \beta_0 : \text{ intercept} \\ \beta_1 : \text{ slope} \end{cases}$$

and  $X_1, \ldots, X_n$  are predictors that are not random;  $\varepsilon_1, \ldots, \varepsilon_n$  are random error terms/disturbance/stochastic terms, and  $Y_1, \ldots, Y_n$  are random response variable. Assumption (Gauss-Markov Conditions):

$$E(\varepsilon_i) = 0, \quad \text{var}(\varepsilon_i) = \sigma^2$$

 $\varepsilon_1, \ldots, \varepsilon_n$  are independent. Using the Gauss-Markov conditions,

$$EY_i = \beta_0 + \beta_1 X_i$$

$$var(Y_i) = \sigma^2$$

$$min Q = \sum \varepsilon_i^2$$

$$min Q = \sum (Y_i - \beta_0 - \beta_1 X_i)^2$$

$$\frac{\partial Q}{\partial \beta_0} = -2 \sum (Y_i - \beta_0 - \beta_1 X_i) = 0$$

$$\frac{\partial Q}{\partial \beta_1} = -2 \sum (Y_i - \beta_0 - \beta_1 X_i) X_i = 0$$

So,

$$\begin{cases} \sum y_i - n\beta_0 - \beta_1 \sum x_i = 0 \\ \sum x_i y_i - \beta_0 \sum x_i - \beta_1 \sum x_i^2 = 0 \end{cases}$$

$$\implies \begin{cases} n\beta_0 + \beta_1 \sum x_i = \sum y_i \\ \beta_0 \sum x_i + \beta_1 \sum x_i^2 = \sum x_i y_i \end{cases} - \text{normal equations}$$

We can solve the above to get  $\hat{\beta}_0, \hat{\beta}_1$ .

$$\begin{pmatrix} n & \sum x_i \\ \sum x_i & \sum x_i^2 \end{pmatrix} \begin{pmatrix} \hat{\beta}_0 \\ \hat{\beta}_1 \end{pmatrix} = \begin{pmatrix} \sum y_i \\ \sum x_i y_i \end{pmatrix}$$
$$\begin{pmatrix} \hat{\beta}_0 \\ \hat{\beta}_1 \end{pmatrix} = \begin{pmatrix} n & \sum x_i \\ \sum x_i & \sum x_i^2 \end{pmatrix}^{-1} \begin{pmatrix} \sum y_i \\ \sum x_i y_i \end{pmatrix}$$

Determinant of the matrix:

$$n\sum x_i^2 - \left(\sum x_i\right)^2 = n\left[\sum x_i^2 - \frac{\left(\sum x_i\right)^2}{n}\right]$$
$$= n\sum (x_i - \overline{x})^2 \ge 0$$

If  $x_1 = x_2 = \ldots = x_n = \overline{x}$  then  $\sum (x_i - \overline{x})^2 = 0$ . From normal equations we get

$$\hat{\beta}_0 = \overline{y} - \hat{\beta}_1 \overline{x}$$
 from (1)

and plug (1) into (2) to obtain

$$\hat{\beta}_{1} = \frac{\sum x_{i}y_{i} - \frac{1}{n}(\sum x_{i})(\sum y_{i})}{\sum x_{i}^{2} - \frac{(\sum x_{i})^{2}}{n}}$$

$$\hat{\beta}_{1} = \frac{\sum (x_{i} - \overline{x})(y_{i} - \overline{y})}{\sum (x_{i} - \overline{x})^{2}}$$

$$\hat{\beta}_{1} = \frac{\sum (x_{i} - \overline{x})y_{i}}{\sum (x_{i} - \overline{x})^{2}}$$

$$\hat{\beta}_{1} = \frac{\sum (y_{i} - \overline{y})x_{i}}{\sum (x_{i} - \overline{x})^{2}}$$

$$(*)$$

or

or

or

or

 $\hat{\beta}_1 = \frac{\sum x_i y_i - n\overline{xy}}{\sum x_i^2 - \frac{(\sum x_i)^2}{n}}$ 

*Note*: From (\*), we have

$$\hat{\beta}_1 = \frac{\sum (x_i - \overline{x})y_i}{\sum (x_i - \overline{x})^2}$$

$$= \frac{(x_1 - \overline{x})y_i}{\sum (x_i - \overline{x})^2} + \dots + \frac{(x_n - \overline{x})y_n}{\sum (x_i - \overline{x})^2}$$

$$= k_1 y_1 + \dots + k_n y_n = \sum_{i=1}^n k_i y_i$$

where  $k_i = \frac{x_i - \overline{x}}{\sum (x_i - \overline{x})^2}$ . Notice that

$$\sum k_i = 0$$

$$\sum k_i^2 = \frac{1}{\sum (x_i - \overline{x})^2}$$

$$\sum k_i x_i = \frac{\sum (x_i - \overline{x}) x_i}{\sum (x_i - \overline{x})^2} = 1$$

Properties of  $\hat{\beta}_1$ :

$$E\hat{\beta}_1 = E \sum_i k_i y_i = \sum_i k_i E y_i$$

$$= \sum_i k_i (\beta_0 + \beta_1 x_i)$$

$$= \beta_0 \sum_i k_i + \beta_1 \sum_i k_i x_i$$

$$= \beta_1 - \text{unbiased}$$

For the variance,

$$\operatorname{var}(\hat{\beta}_1) = \operatorname{var}\left(\sum k_i y_i\right)$$
$$= \sum k_i^2 \operatorname{var}(Y_i)$$
$$= \frac{\sigma^2}{\sum (x_i - \overline{x})^2}$$

Properties of  $\hat{\beta}_0$ :

$$\hat{\beta}_0 = \overline{y} - \hat{\beta}_1 \overline{x}$$

$$= \sum_{i=1}^{n} \frac{y_i}{n} - \overline{x} \sum_{i=1}^{n} k_i y_i$$

$$= \sum_{i=1}^{n} l_i y_i$$

where  $l_i = \frac{1}{n} - \overline{x}k_i$  and the properties of  $l_i$  are

$$\sum l_i = 1$$

$$\sum l_i^2 = \sum \left(\frac{1}{n} - \overline{x}k_i\right)^2 = \sum \left(\frac{1}{n^2} + \overline{x}^2k_i^2 - \frac{2}{n}\overline{x}k_i\right)$$

$$= \frac{1}{n} + \frac{\overline{x}^2}{\sum (x_i - \overline{x})^2}$$

$$\sum l_i x_i = 0$$

Now, we can easily show that  $\hat{\beta}_0$  is unbiased

$$E\hat{\beta}_0 = E \sum_i l_i y_i = \sum_i l_i E y_i$$
  
= 
$$\sum_i l_i (\beta_0 + \beta_1 x_i) = \beta_0 \sum_i l_i + \beta_1 \sum_i l_i x_i$$
  
= 
$$\beta_0$$

Thus,

$$\operatorname{var}\left(\hat{\beta}_{0}\right) = \operatorname{var}\left(\sum l_{i}y_{i}\right) = \sigma^{2} \sum l_{i}^{2} = \sigma^{2}\left(\frac{1}{n} + \frac{\overline{x}^{2}}{\sum(x_{i} - \overline{x})^{2}}\right)$$

The fitted value is

$$\hat{y}_i = \hat{\beta}_0 + \hat{\beta}_1 x_i = \overline{y} + \hat{\beta}_1 (x_i - \overline{x})$$

and the residual is defined as

$$e_i = y_i - \hat{y}_i$$

with properties

$$\sum e_i = 0$$

$$\sum e_i x_i = 0$$

$$\sum e_i \hat{y}_i = 0$$

#### Estimation Using MML:

Assume  $\varepsilon_1, \ldots, \varepsilon_n \stackrel{\text{i.i.d}}{\sim} N(0, \sigma)$ . Then  $Y_i \sim N(\beta_0 + \beta_1 X_i, \sigma)$ . The log-likelihood function is

$$\ln L = -\frac{n}{2} \ln 2\pi \sigma^2 - \frac{1}{2\sigma^2} \sum (y_i - \beta_0 - \beta_1 x_i)^2$$

So, we need to solve

$$\frac{\partial \ln L}{\partial \beta_0} = 0, \quad \frac{\partial \ln L}{\partial \beta_1} = 0$$

to get  $\hat{\beta}_0, \hat{\beta}_1$  which are the same as least squares method.

$$\frac{\partial \ln L}{\partial \sigma^2} = -\frac{n}{2\sigma^2} + \frac{1}{2\sigma^4} \sum (y_i - \beta_0 - \beta_1 x_i)^2 = 0$$

$$\hat{\sigma}^2 = \frac{\sum e_i^2}{n}$$

Then,

$$\sum (y_i - \overline{y})^2 = \sum \left( \underbrace{y_i - \hat{y}_i}_{e_i} + \hat{y}_i + \overline{y} \right)^2$$

in which we expand to get

$$\underbrace{\sum (y_i - \overline{y})^2}_{\text{SST}} = \underbrace{\sum e_i^2}_{\text{SSE}} + \underbrace{\sum (\hat{y}_i - \overline{y})^2}_{\text{SSR}}$$

in which

SST: sum of squares total
SSE: sum of squares error
SSR: sum of squares regression

# §3 Lec 3: Oct 1, 2021

### §3.1 Gauss-Markov Theorem

Recall

$$\hat{\beta}_1 = \sum k_i Y_i$$

where  $k_i = \frac{x_i - \overline{x}}{\sum (x_i - \overline{x})^2}$ . Consider now

$$b_1 = \sum a_i Y_i$$

which is another unbiased estimator of  $\beta_1$ . Then  $Eb_1 = \beta_1$  or  $E \sum a_i Y_i = \beta_1$ . So

$$\beta_1 = \sum a_i EY_i$$

$$= \sum a_i (\beta_0 + \beta_1 X_i)$$

$$= \beta_0 \sum a_i + \beta_1 \sum a_i X_i$$

Thus,

$$\begin{cases} \sum a_i = 0\\ \sum a_i x_i = 1 \end{cases}$$

and we know that

$$\operatorname{var}(b_1) = \operatorname{var}\left(\sum_{i=1}^n a_i Y_i\right) = \sigma^2 \sum a_i^2$$

and

$$\operatorname{var}(\hat{\beta}_1) = \sigma^2 \sum k_i^2 = \frac{\sigma^2}{\sum (x_i - \overline{x})^2}$$

Now let  $a_i = k_i + d_i$ . Then,

$$var(b_1) = \sigma^2 \sum_i (k_i + d_i)^2$$
$$= \sigma^2 \sum_i k_i^2 + \sigma^2 \sum_i d_i^2 + 2\sigma^2 \sum_i k_i d_i$$

We need to show  $\sum k_i d_i = 0$ .

$$\sum k_i(a_i - k_i) = \sum k_i a_i - \sum k_i^2$$

$$= \frac{\sum (x_i - \overline{x})a_i}{\sum (x_i - \overline{x})^2} - \frac{1}{\sum (x_i - \overline{x})^2}$$

$$= \frac{\sum x_i a_i}{\sum (x_i - \overline{x})^2} - \frac{\overline{x} \sum a_i}{\sum (x_i - \overline{x})^2} - \frac{1}{\sum (x_i - \overline{x})^2}$$

$$= 0$$

So  $var(b_1) \ge var(\hat{\beta}_1)$  and therefore  $\hat{\beta}_1$  is the best linear unbiased estimator (BLUE).

## §3.2 Estimation of Variance

Using MML

$$\hat{\sigma}^2 = \frac{\sum e_i^2}{n}$$

Is it unbiased?

$$E\hat{\sigma}^2 = \frac{\sum Ee_i^2}{n} = \frac{\sum \left[\text{var}(e_i) + (Ee_i)^2\right]}{n}$$

Note: 
$$e_i = Y_i - \hat{Y}_i = Y_i - \hat{\beta}_0 - \hat{\beta}_1 X_i$$
. So

$$Ee_i = E\left[Y_i - \hat{\beta}_0 - \hat{\beta}_1 X_i\right] = (\beta_0 + \beta_1 X_i) - (\beta_0 + \beta_1 X_i) = 0$$

Then,

$$E\hat{\sigma}^2 = \frac{\sum \text{var}(e_i)}{n}$$

Notice that

$$e_i = Y_i - \hat{\beta}_0 - \hat{\beta}_1 X_i$$

or

$$e_i = Y_i - \overline{Y} - \hat{\beta}_1(X_i - \overline{X})$$

where  $\hat{Y}_i = \overline{Y} + \hat{\beta}_1(X_i - \overline{X})$ . Substitute in and we get

$$\operatorname{var}(e_{i}) = \operatorname{var}\left[Y_{i} - \overline{Y} - \hat{\beta}_{1}(X_{i} - \overline{X})\right]$$

$$= \operatorname{var}(Y_{i}) + \operatorname{var}(\overline{Y}) + (X_{i} - \overline{X})^{2} \operatorname{var}(\hat{\beta}_{1}) - 2\operatorname{cov}(Y_{i}, \overline{Y}) - 2(X_{i} - \overline{X})\operatorname{cov}(Y_{i}, \hat{\beta}_{1})$$

$$+ 2(X_{i} - \overline{X})\operatorname{cov}(\overline{Y}, \hat{\beta}_{1})$$

Let's compute each term there.

$$\begin{aligned} Y_i &= \beta_0 + \beta_1 X_i + \varepsilon_i \\ \operatorname{var}(Y_i) &= \sigma^2 \\ \overline{Y} &= \beta_0 + \beta_1 \overline{X} + \frac{\sum \varepsilon_i}{n} \\ \operatorname{var}(\overline{Y}) &= \frac{\sigma^2}{n} \\ \operatorname{cov}(Y_i, \overline{Y}) &= \operatorname{cov}\left(Y_i, \frac{Y_1 + \ldots + Y_i + \ldots + Y_n}{n}\right) \\ &= \frac{1}{n} \operatorname{cov}(Y_i, Y_1) + \ldots + \frac{1}{n} \operatorname{cov}(Y_i, Y_i) + \ldots + \frac{1}{n} \operatorname{cov}(Y_i, Y_n) \\ &= \frac{\sigma^2}{n} \\ \operatorname{cov}(Y_i, \hat{\beta}_1) &= \operatorname{cov}(Y_i, \sum k_i Y_i) \\ &= \operatorname{cov}(Y_i, k_1 Y_1) + \ldots + \operatorname{cov}(Y_i, k_i Y_i) + \ldots + \operatorname{cov}(Y_i, k_n Y_n) \\ &= k_1 \operatorname{cov}(Y_i, Y_1) + \ldots + k_i \operatorname{cov}(Y_i, Y_i) + \ldots + k_n \operatorname{cov}(Y_1, Y_n) \\ &= \sigma^2 k_i = \sigma^2 \frac{x_i - \overline{x}}{\sum (x_i - \overline{x})^2} \end{aligned}$$

*Note*: A property of covariance

$$cov(aY, bQ) = ab cov(Y, Q)$$

And for the last term,

$$cov(\overline{Y}, \hat{\beta}_1) = cov\left(\frac{Y_1 + \dots + Y_n}{n}, k_1 Y_1 + \dots + k_n Y_n\right)$$

$$= cov(\frac{Y_1}{n}, k_1 Y_1 + \dots + k_n Y_n) + \dots + cov(\frac{Y_n}{n}, k_1 Y_1 + \dots + k_n Y_n)$$

$$= \frac{\sigma^2}{n} k_1 + \frac{\sigma^2}{n} k_2 + \dots + \frac{\sigma^2}{n} k_n$$

$$= \frac{\sigma^2}{n} \sum k_i = 0$$

Now, we're ready to compute the variance

$$\operatorname{var}(e_i) = \sigma^2 + \frac{\sigma^2}{n} + \frac{\sigma^2 (x_i - \overline{x})^2}{\sum (x_i - \overline{x})^2} - \frac{2\sigma^2}{n} - \frac{2\sigma^2 (x_i - \overline{x})^2}{\sum (x_i - \overline{x})^2}$$
$$= \sigma^2 \left( 1 - \frac{1}{n} - \frac{(x_i - \overline{x})^2}{\sum (x_i - \overline{x})^2} \right)$$

Therefore,

$$E\hat{\sigma}^2 = \frac{\sum \operatorname{var}(e_i)}{n} = \sigma^2 \frac{\sum_{i=1}^n \left(1 - \frac{1}{n} - \frac{(x_i - \overline{x})^2}{\sum (x_i - \overline{x})^2}\right)}{n}$$
$$= \frac{(n-2)}{n} \sigma^2$$

It follows that the unbiased estimator of  $\sigma^2$  is

$$S_e^2 = \frac{n}{n-2}\sigma^2 = \frac{\sum e_i^2}{n-2}$$

## §3.3 Distribution Theory

Let  $Y_i = \beta_0 + \beta_1 X_i + \varepsilon_i$  and we assume  $\varepsilon_1, \dots, \varepsilon_n \stackrel{\text{i.i.d}}{\sim} N(0, \sigma)$ 

$$\hat{\beta}_1 = \sum k_i Y_i \implies \hat{\beta}_1 \sim N\left(\beta_1, \frac{\sigma}{\sqrt{\sum (x_i - \overline{x})^2}}\right)$$

$$\hat{\beta}_0 = \sum l_i Y_i \implies \hat{\beta}_0 \sim N\left(\beta_0, \sigma \sqrt{\frac{1}{n} + \frac{\overline{x}^2}{\sum (x_i - \overline{x})^2}}\right)$$

We will show  $\frac{(n-2)S_e^2}{\sigma^2} \sim \mathcal{X}_{n-2}^2$  in the next lecture.

# $\S4$ Lec 4: Oct 4, 2021

### §4.1 Centered Model

Consider the model:  $Y_i = \beta_0 + \beta_1 X_i + \varepsilon_i$ , i = 1, ..., n and Gauss-Markov conditions hold, i.e.,

$$E\left[\varepsilon_{i}\right] = 0$$
$$\operatorname{var}\left[\varepsilon_{i}\right] = \sigma^{2}$$

for  $i=1,\ldots,n$  and  $\varepsilon_1,\ldots,\varepsilon_n$  are independent (we assume  $\varepsilon_1,\ldots,\varepsilon_n\stackrel{\text{i.i.d}}{\sim} N(0,\sigma)$ ). This is non-centered model. Let's look at a centered model

$$\begin{split} Y_i &= \beta_0 + \beta_1 X_i \pm \beta_1 \overline{X} + \varepsilon_i \\ Y_i &= \beta_0 + \beta_1 \overline{X} + \beta_1 (X_i - \overline{X}) + \varepsilon_i \\ Y_i &= \gamma_0 + \beta_1 Z_i + \varepsilon_i \quad - \text{centered model} \end{split}$$

where  $\gamma_0 = \beta_0 + \beta_1 \overline{X}$  and  $Z_i = X_i - \overline{X}$ . <u>Note</u>:  $\sum z_i = \sum (x_i - \overline{x}) = 0$  and  $\overline{z} = 0$ . So,

$$\hat{\beta}_1 = \frac{\sum (z_i - \overline{z})y_i}{\sum (z_i - \overline{z})^2} = \frac{\sum z_i y_i}{\sum z_i^2} = \frac{\sum (x_i - \overline{x})y_i}{\sum (x_i - \overline{x})^2} - \text{same as non-centered model}$$

$$\hat{\gamma}_0 = \overline{y} - \hat{\beta}_1 \overline{z} = \overline{y}$$

Notice  $\hat{Y}_i = \overline{Y} - \hat{\beta}_1(X_i - \overline{X})$  which is the same as  $\hat{Y}_i$  of the non-centered model.

## §4.2 Distribution Theory Using the Centered Model

Have

$$Y_{i} \sim N\left(\gamma_{0} + \beta_{1}\left(X_{i} - \overline{X}\right), \sigma\right)$$

$$\hat{\beta}_{1} \sim \left(\beta_{1}, \frac{\sigma}{\sqrt{\sum(x_{i} - \overline{x})^{2}}}\right)$$

$$\hat{\gamma}_{0} = \overline{Y} \sim N\left(\gamma_{0}, \frac{\sigma}{\sqrt{n}}\right)$$

Now, let's show that  $\frac{(n-2)S_e^2}{\sigma^2} \sim \mathcal{X}_{n-2}^2$ . We have

$$\frac{Y_i - \gamma_0 - \beta_1(X_i - \overline{X})}{\sigma} \sim N(0, 1)$$
$$\frac{\left[Y_i - \gamma_0 - \beta_1(X_i - \overline{X})\right]^2}{\sigma^2} \sim \mathcal{X}_1^2$$

It follows that

$$\frac{\sum_{i=1}^{n} \left[ Y_i - \gamma_0 - \beta_1 (X_i - \overline{X}) \right]^2}{\sigma^2} \sim \mathcal{X}_n^2$$

Notice that  $\frac{(n-2)S_e^2}{\sigma^2} = \frac{\sum e_i^2}{\sigma^2}$ . Let's manipulate this expression. First, let

$$L = \frac{\sum \left[ Y_i - \gamma_0 - \beta_1 (X_i - \overline{X}) \pm \hat{\gamma}_0 \pm \hat{\beta}_1 (X_i - \overline{X}) \right]^2}{\sigma^2}$$

Then,

$$L = \frac{\sum \left[ y_i - \hat{\gamma}_0 - \hat{\beta}_1(x_i - \overline{x}) + (\hat{\gamma}_0 - \gamma_0) + (\hat{\beta}_1 - \beta_1)(x_i - \overline{x}) \right]^2}{\sigma^2}$$

$$= \frac{\sum \left[ e_i + (\hat{\gamma}_0 - \gamma_0) + (\hat{\beta}_1 - \beta_1)(x_i - \overline{x}) \right]^2}{\sigma^2}$$

$$= \frac{\sum e_i^2}{\sigma^2} + \frac{n(\hat{\gamma}_0 - \gamma_0)^2}{\sigma^2} + \frac{(\hat{\beta}_1 - \beta_1)^2 \sum (x_i - \overline{x})^2}{\sigma^2} + \frac{2(\hat{\gamma}_0 - \gamma_0) \sum e_i}{\sigma^2}$$

$$+ \frac{2(\hat{\beta}_1 - \beta_1) \sum e_i(x_i - \overline{x})}{\sigma^2} + \frac{2(\hat{\gamma}_0 - \gamma_0)(\hat{\beta}_1 - \beta_1) \sum (x_i - \overline{x})}{\sigma^2}$$

So far,

$$\underbrace{\frac{\sum \left[y_i - \gamma_0 - \beta_1(x_i - \overline{x})\right]^2}{\sigma^2}}_{\mathcal{X}_n^2} = \underbrace{\frac{(n-2)S_e^2}{\sigma^2}}_{?} + \underbrace{\frac{\hat{\gamma}_0 - \gamma_0}{\sigma/\sqrt{n}}}_{\mathcal{X}_1^2} + \underbrace{\left[\frac{\hat{\beta}_1 - \beta_1}{\sigma/\sqrt{\sum (x_i - \overline{x})^2}}\right]^2}_{\mathcal{X}_1^2}$$

$$Q = Q_1 + Q_2 + Q_3$$

Let's use moment generating function to find "?". Notice that  $Q_1, Q_2, Q_3$  are independent \_\_\_\_\_\_ why

$$\begin{split} M_Q(t) &= M_{Q_1 + Q_2 + Q_3} \\ M_Q(t) &= M_{Q_1}(t) \cdot M_{Q_2}(t) \cdot M_{Q_3}(t) \end{split}$$

We have

$$Q \sim \mathcal{X}_n^2 \implies M_Q(t) = (1 - 2t)^{-\frac{n}{2}}$$

$$Q_2 \sim \mathcal{X}_1^2 \implies M_{Q_2}(t) = (1 - 2t)^{-\frac{1}{2}}$$

$$Q_3 \sim \mathcal{X}_1^2 \implies M_{Q_3}(t) = (1 - 2t)^{-\frac{1}{2}}$$

$$\implies M_{Q_1}(t) = (1 - 2t)^{\frac{-n+2}{2}}$$

$$\implies Q_1 = \frac{(n-2)S_e^2}{\sigma^2} \sim \mathcal{X}_{n-2}^2$$

*Note*: If  $Y \sim \Gamma(\alpha, \beta)$  then

$$M_{V}(t) = (1 - \beta t)^{-\alpha}$$

and

$$M_{cY}(t) = M_Y(ct)$$

Let's now find the distribution of  $s_e^2$ .

$$S_e^2 = \frac{\sigma^2}{n-2}Q_1$$

$$M_{S_e^2}(t) = M_{\frac{\sigma^2}{n-2}Q_1}(t) = M_{Q_1}\left(\frac{\sigma^2}{n-2}t\right)$$

$$M_{S_e^2}(t) = \left(1 - \frac{2\sigma^2}{n-2}t\right)^{\frac{-n+2}{2}}$$

Therefore,

$$S_e^2 \sim \Gamma\left(\frac{n-2}{2}, \frac{2\sigma^2}{n-2}\right)$$
$$ES_e^2 = \sigma^2, \quad \text{var}(S_e^2) = \frac{2\sigma^4}{n-2}$$

Another way to show this result is to use the non-centered model

$$\frac{\sum \left(Y_i - \beta_0 - \beta_1 X_i \pm \hat{\beta}_0 \pm \hat{\beta}_1 X_i\right)^2}{\sigma^2}$$

# $\S 5$ Lec 5: Oct 6, 2021

### §5.1 Distribution Theory Using Non-Centered Model

Recall that we want to show  $\frac{(n-2)S_e^2}{\sigma^2} \sim \mathcal{X}_{n-2}^2$  using the non-centered model  $Y_i = \beta_0 + \beta_1 X_i + \varepsilon_i$  for  $\varepsilon_1, \ldots, \varepsilon_n \stackrel{\text{i.i.d}}{\sim} N(0, \sigma)$ . Then,  $Y_i \sim N(\beta_0 + \beta_1 X_i, \sigma)$ . Let

$$M = \frac{\sum \left( Y_i - \beta_0 - \beta_1 X_i \pm \hat{\beta}_0 \pm \hat{\beta}_1 X_i \right)^2}{\sigma^2} \sim \mathcal{X}_n^2$$

Then,

$$\begin{split} M &= \frac{\sum \left(y_{i} - \hat{\beta}_{0} - \hat{\beta}_{1}x_{i} + (\hat{\beta}_{0} - \beta_{0}) + (\hat{\beta}_{1} - \beta_{1})x_{i}\right)^{2}}{\sigma^{2}} \\ &= \frac{\sum e_{i}^{2}}{\sigma^{2}} + \frac{n(\hat{\beta}_{0} - \beta_{0})^{2}}{\sigma^{2}} + \frac{(\hat{\beta}_{1} - \beta_{1})^{2} \sum x_{i}^{2}}{\sigma^{2}} + \frac{2(\hat{\beta}_{0} - \beta_{0}) \sum e_{i}}{\sigma^{2}} + \frac{2(\hat{\beta}_{1} - \beta_{1}) \sum e_{i}x_{i}}{\sigma^{2}} \\ &+ \frac{2(\hat{\beta}_{0} - \beta_{0})(\hat{\beta}_{1} - \beta_{1}) \sum x_{i}}{\sigma^{2}} \\ &= \underbrace{\sum e_{i}^{2}}_{\frac{(n-2)S_{e}^{2}}{2}} + \underbrace{\frac{n(\hat{\beta}_{0} - \beta_{0})^{2}}{\sigma^{2}} + \frac{(\hat{\beta}_{1} - \beta_{1})^{2} \sum x_{i}^{2}}{\sigma^{2}} + \frac{2(\hat{\beta}_{0} - \beta_{0})(\hat{\beta}_{1} - \beta_{1}) \sum x_{i}}{\sigma^{2}} \end{split} \tag{***}$$

Let  $D = \hat{\beta}_0 + \hat{\beta}_1 \overline{X} = \overline{Y}$  and consider

$$\frac{(\hat{\beta}_1 - \beta_1)^2}{\operatorname{var}(\hat{\beta}_1)} + \frac{(D - (\beta_0 + \beta_1 \overline{x}))^2}{\operatorname{var}(D)} \tag{*}$$

<u>Note</u>:  $\hat{\beta}_1 \sim N\left(\beta_1, \frac{\sigma}{\sqrt{\sum (x_i - \overline{x})^2}}\right)$  and

$$Y_i = \beta_0 + \beta_1 X_i + \varepsilon_i$$

$$\overline{Y} = \frac{\sum Y_i}{n} = \beta_0 + \beta_1 \overline{X} + \frac{\sum \varepsilon_i}{n}$$

So  $\overline{Y} \sim N\left(\beta_0 + \beta_1 \overline{X}, \frac{\sigma}{\sqrt{n}}\right)$  and thus  $\frac{D - (\beta_0 + \beta_1 \overline{X})}{\sigma/\sqrt{n}} \sim N(0, 1)$ . It follows that each term in (\*) follows chi-square distribution with 1 degree of freedom. Now, we have

$$(*) = \frac{(\hat{\beta}_1 - \beta_1)^2}{\sigma^2} \sum_{i} (x_i - \overline{x})^2 + \frac{n(\hat{\beta}_0 - \beta_0)^2}{\sigma^2} + \frac{(\hat{\beta}_1 - \beta_1)^2}{\sigma^2} n \overline{x}^2 + \frac{2(\hat{\beta}_0 - \beta_0)(\hat{\beta}_1 - \beta_1)}{\sigma^2} \sum_{i} x_i$$

$$= \frac{(\hat{\beta}_1 - \beta_1)^2 (\sum_{i} x_i^2 - n \overline{x}^2)}{\sigma^2} + \frac{n(\hat{\beta}_0 - \beta_0)^2}{\sigma^2} + \frac{(\hat{\beta}_1 - \beta_1)^2 n \overline{x}^2}{\sigma^2} + \frac{2(\hat{\beta}_0 - \beta_0)(\hat{\beta}_1 - \beta_1) \sum_{i} x_i}{\sigma^2}$$

which is equivalent to the last three terms of (\*\*). We just need to show that

$$cov(\overline{Y}, \hat{\beta}_1) = 0$$
$$cov(\overline{Y}, e_i) = 0$$
$$cov(\hat{\beta}_1, e_i) = 0$$

Remark 5.1. Under normality, zero covariance implies independence.

### §5.2 A Note on Gamma Distribution

Let  $Q \sim \Gamma(\alpha, \beta)$ . Then

$$EQ = \alpha\beta$$
$$var(Q) = \alpha\beta^{2}$$
$$M_{Q}(t) = (1 - \beta t)^{-\alpha}$$
$$EQ^{k} = \frac{\Gamma(\alpha + k)\beta^{k}}{\Gamma(\alpha)}$$

where

$$\Gamma(\alpha) = \int_0^\infty x^{\alpha - 1} e^{-x} \, dx$$

is the Gamma function.

Property:

$$\Gamma(\alpha) = (\alpha - 1)\Gamma(\alpha - 1)$$
 
$$\Gamma(\alpha + 1) = \alpha\Gamma(\alpha)$$

If  $\alpha$  is an integer, then

$$\Gamma(\alpha) = (\alpha - 1)!$$

Recall that  $S_e^2 \sim \Gamma\left(\frac{n-2}{2}, \frac{2\sigma^2}{n-2}\right)$ 

$$ES_e^2 = \sigma^2$$
,  $var(S_e^2) = \frac{2\sigma^4}{n-2}$ 

Is  $S_e$  unbiased estimator of  $\sigma$ ?

$$ES_e = E \left[ S_e^2 \right]^{\frac{1}{2}}$$

$$= \frac{\Gamma \left( \frac{n-2}{2} + \frac{1}{2} \right) \left( \frac{2\sigma^2}{n-2} \right)^{\frac{1}{2}}}{\Gamma \left( \frac{n-2}{2} \right)}$$

$$= \sigma \sqrt{\frac{2}{n-2}} \Gamma \left( \frac{n-1}{2} \right) / \Gamma \left( \frac{n-2}{2} \right)$$

$$= \sigma A$$

Thus, it's biased and we can adjust the result to be unbiased, i.e.,  $\frac{S_e}{A}$ . If  $Y \sim \mathcal{X}_n^2$ , then

$$M_Y(t) = (1 - 2t)^{-\frac{n}{2}}$$

which is  $\Gamma\left(\frac{n}{2},2\right)$ .

### §5.3 Coefficient of Determination

Recall

$$\underbrace{\sum (y_i - \overline{y})^2}_{\text{SST}} = \underbrace{\sum e_i^2}_{\text{SSE}} + \underbrace{\sum (\hat{y}_i - \overline{y})^2}_{\text{SSR}}$$

where  $\hat{Y}_i = \overline{y} + \hat{\beta}_1(x_i - \overline{x})$ . We define  $R^2$  as

$$R^2 = \frac{\text{SSR}}{\text{SST}}$$
 or  $R^2 = 1 - \frac{\text{SSE}}{\text{SST}}$ 

and  $0 \le R^2 \le 1$ . We have

$$\operatorname{var}(\hat{Y}_i) = \operatorname{var}\left(\overline{y} + \hat{\beta}_1(x_i - \overline{x})\right)$$
$$= \sigma^2 \left(\frac{1}{n} + \frac{(x_i - \overline{x})^2}{\sum (x_i - \overline{x})^2}\right)$$

Another way to show this is to express  $\hat{Y}_i$  as a linear combination of  $Y_1, \ldots, Y_n$ .

$$\begin{split} \hat{Y}_i &= \overline{y} + \hat{\beta}_1(x_i - \overline{x}) \\ &= \frac{\sum y_j}{n} + (x_i - \overline{x}) \sum k_j y_j \\ &= \sum \left[ \frac{1}{n} + (x_i - \overline{x})k_j \right] y_j \\ \text{var}(\hat{Y}_i) &= \sigma^2 \sum \left[ \frac{1}{n} + (x_i - \overline{x})k_j \right]^2 \\ &= \sigma^2 \sum \left[ \frac{1}{n^2} + (x_i - \overline{x})^2 k_j^2 + \frac{2}{n} (x_i - \overline{x})k_j \right] \\ &= \sigma^2 \left( \frac{1}{n} + \frac{(x_i - \overline{x})^2}{\sum (x_i - \overline{x})^2} \right) \end{split}$$

Consider

$$e_i = y_i - \hat{y}_i = y_i - \overline{y} - \hat{\beta}_1(x_i - \overline{x}) = \sum a_l y_l - \frac{\sum y_l}{n} - (x_i - \overline{x}) \sum k_l y_l = \sum \left[ a_l - \frac{1}{n} - (x_i - \overline{x})k_l \right] y_l$$

where

$$a_l = \begin{cases} 1, & \text{if } l = i \\ 0, & \text{otherwise} \end{cases}$$

# $\S6$ Lec 6: Oct 8, 2021

## §6.1 Variance & Covariance Operations

Have

$$\operatorname{cov}\left(\sum a_i Y_i, \sum b_j Y_j\right) = \sum_{i=1}^n \sum_{i=1}^n a_i b_j \operatorname{cov}(Y_i, Y_j) = \sum a_i b_i \operatorname{cov}(Y_i, Y_i) = \sigma^2 \sum a_i b_i$$

because  $Y_1, \ldots, Y_n$  are independent.

#### Example 6.1

Consider  $\hat{\beta}_0$  and  $\hat{\beta}_1$ 

$$cov(\hat{\beta}_0, \hat{\beta}_1) = cov\left(\sum l_i Y_i, \sum k_i Y_j\right)$$

$$= \sigma^2 \sum l_i k_i$$

$$= \sigma^2 \sum \left[\left(\frac{1}{n} - k_i \overline{x}\right) k_i\right]$$

$$= \sigma^2 \frac{1}{n} \sum k_i - \sigma^2 \overline{x} \sum k_i^2$$

$$= -\frac{\sigma^2 \overline{x}}{\sum (x_i - \overline{x})^2}$$

Or

$$\begin{aligned} \operatorname{cov}\left(\hat{\beta}_{0}, \hat{\beta}_{1}\right) &= \operatorname{cov}\left(\overline{Y} - \hat{\beta}_{1}\overline{X}, \hat{\beta}_{1}\right) \\ &= \operatorname{cov}\left(\overline{Y}, \hat{\beta}_{1}\right) - \overline{X}\operatorname{var}(\hat{\beta}_{1}) \\ &= \frac{-\overline{x}\sigma^{2}}{\sum(x_{i} - \overline{x})^{2}} \end{aligned}$$

### Example 6.2

Consider  $\hat{Y}_i$  and  $\hat{Y}_j$ 

$$cov\left(\hat{Y}_{i}, \hat{Y}_{j}\right) = cov\left(\overline{y} + \hat{\beta}_{1}(x_{i} - \overline{x}), \overline{y} + \hat{\beta}_{1}(x_{j} - \overline{x})\right)$$

$$= \frac{\sigma^{2}}{n} + 0 + 0 + \frac{(x_{i} - \overline{x})(x_{j} - \overline{x})}{\sum (x_{i} - \overline{x})^{2}}\sigma^{2}$$

$$= \sigma^{2}\left(\frac{1}{n} + \frac{(x_{i} - \overline{x})(x_{j} - \overline{x})}{\sum (x_{i} - \overline{x})^{2}}\right)$$

When i = j,

$$\operatorname{var}(\hat{Y}_i) = \sigma^2 \left( \frac{1}{n} + \frac{(x_i - \overline{x})^2}{\sum (x_i - \overline{x})^2} \right)$$

### Example 6.3 (Cont'd)

Notice that

$$\hat{Y}_i = \overline{y} + \hat{\beta}_1(x_i - \overline{x}) = \frac{\sum y_l}{n} + (x_i - \overline{x}) \sum k_l y_l$$

$$= \sum \left[ \frac{1}{n} + (x_i - \overline{x})k_l \right] y_l = \sum a_l y_l$$

$$\hat{Y}_j = \dots = \sum b_v y_v$$

$$\operatorname{cov}\left(\hat{Y}_i, \hat{Y}_j\right) = \sigma^2 \sum a_l b_l$$

$$= \sigma^2 \sum \left[ \frac{1}{n} + (x_i - \overline{x})k_l \right] \left[ \frac{1}{n} + (x_j - \overline{x})k_l \right]$$

$$= \sigma^2 \left( \frac{1}{n} + \frac{(x_i - \overline{x})(x_j - \overline{x})}{\sum (x_i - \overline{x})^2} \right)$$

### §6.2 Inference

Construct a confidence interval  $1 - \alpha$  for  $\beta_1$ 

$$P\left(L \le \beta_1 \le U\right) = 1 - \alpha$$

Know

$$\hat{\beta}_1 \sim N\left(\beta_1, \frac{\sigma}{\sqrt{\sum (x_i - \overline{x})^2}}\right)$$

and

$$\frac{(n-2)S_e^2}{\sigma^2} \sim \mathcal{X}_{n-2}^2$$

Consider

$$\operatorname{cov}\left(\hat{\beta}_1, e_i\right) = 0$$

Under normality, since their covariance is 0,  $\hat{\beta}_1$  and  $S_e^2$  are independent. Thus,

$$\frac{\frac{\hat{\beta}_1 - \beta_1}{\sigma/\sqrt{\sum (x_i - \overline{x})^2}}}{\sqrt{\frac{(n-2)S_e^2}{\sigma^2}/(n-2)}} = \frac{\hat{\beta}_1 - \beta_1}{S_e/\sqrt{\sum (x_i - \overline{x})^2}} \sim t_{n-2}$$

Pivot Method:

$$P\left(-t_{\frac{\alpha}{2};n-2} \le \frac{\hat{\beta}_1 - \beta_1}{S_e/\sqrt{\sum (x_i - \overline{x})^2}} \le t_{\frac{\alpha}{2};n-2}\right) = 1 - \alpha$$

and after some manipulation we get

$$P\left(\hat{\beta}_1 - t_{\frac{\alpha}{2}; n-2} \cdot \frac{S_e}{\sqrt{\sum (x_i - \overline{x})^2}} \le \beta_1 \le \hat{\beta}_1 + t_{\frac{\alpha}{2}; n-2} \cdot \frac{S_e}{\sqrt{\sum (x_i - \overline{x})^2}}\right) = 1 - \alpha$$

We are  $1 - \alpha$  confident that

$$\beta_1 \in \left[ \hat{\beta}_1 \pm t_{\frac{\alpha}{2}; n-2} \cdot \frac{S_e}{\sqrt{\sum (x_i - \overline{x})^2}} \right]$$

For  $\hat{\beta}_0$ ,

$$\hat{\beta}_0 \sim N \left( \beta_0, \sigma \sqrt{\frac{1}{n} + \frac{\overline{x}^2}{\sum (x_i - \overline{x})^2}} \right)$$

and we proceed similarly to obtain

$$\beta_0 \in \left[ \hat{\beta}_0 \pm t_{\frac{\alpha}{2};n-2} \cdot S_e \sqrt{\frac{1}{n} + \frac{\overline{x}^2}{\sum (x_i - \overline{x})^2}} \right]$$

Say if we want to construct a confidence interval for  $\beta_0 - 2\beta_1$ :

$$\operatorname{var}(\hat{\beta}_{0} - 2\hat{\beta}_{1}) = \operatorname{var}(\hat{\beta}_{0}) + 4\operatorname{var}(\hat{\beta}_{1}) - 4\operatorname{cov}(\hat{\beta}_{0}, \hat{\beta}_{1})$$

$$= \sigma^{2} \left[ \frac{1}{n} + \frac{\overline{x}^{2}}{\sum (x_{i} - \overline{x})^{2}} + \frac{4}{\sum (x_{i} - \overline{x})^{2}} + \frac{4\overline{x}}{\sum (x_{i} - \overline{x})^{2}} \right]$$

$$= \sigma^{2} \left[ \frac{1}{n} + \frac{(\overline{x} + 2)^{2}}{\sum (x_{i} - \overline{x})^{2}} \right]$$

So,

$$\hat{\beta}_0 - 2\hat{\beta}_1 \sim N\left(\beta_0 - 2\beta_1, \sigma\sqrt{\frac{1}{n} + \frac{(\overline{x} + 2)^2}{\sum (x_i - \overline{x})^2}}\right)$$

Thus, the C.I. is

$$\beta_0 - 2\beta_1 \in \left[ \hat{\beta}_0 - 2\hat{\beta}_1 \pm t_{\frac{\alpha}{2}; n-2} \cdot S_e \sqrt{\frac{1}{n} + \frac{(\overline{x} + 2)^2}{\sum (x_i - \overline{x})^2}} \right]$$

### §6.3 Prediction Interval

Prediction interval for  $Y_0$  when  $X = X_0$ . Let's begin with error of prediction:  $Y_0 - \hat{Y}_0$ . We know

- $Y_i = \beta_0 + \beta_1 X_i + \varepsilon_i$
- $Y_0 = \beta_0 + \beta_1 X_0 + \varepsilon_0$
- $\hat{Y}_0 = \hat{\beta}_0 + \hat{\beta}_1 X_0$

So

$$E(Y_0 - \hat{Y}_0) = 0$$

$$var(Y_0 - \hat{Y}_0) = var(Y_0) + var(\hat{Y}_0) - 2 cov(Y_0, \hat{Y}_0)$$

$$= \sigma^2 \left( 1 + \frac{1}{n} + \frac{(x_0 - \overline{x})^2}{\sum (x_i - \overline{x})^2} \right)$$

We apply the same procedure in the inference section

$$\left. \begin{array}{l} Y_0 - \hat{Y}_0 \sim N\left(0, \sigma\sqrt{1 + \frac{1}{n} + \frac{(x_0 - \overline{x})^2}{\sum (x_i - \overline{x})^2}}\right) \\ \frac{(n - 2)S_e^2}{\sigma^2} \sim \mathcal{X}_{n - 2}^2 \end{array} \right. \\ \\ \Longrightarrow \left. \begin{array}{l} Y_0 \in \hat{Y}_0 \pm t_{\frac{\alpha}{2}; n - 2} S_e \sqrt{1 + \frac{1}{n} + \frac{(x_0 - \overline{x})^2}{\sum (x_i - \overline{x})^2}} \\ \end{array} \right) \\ \end{array}$$

C.I. for  $EY_0$  for a given  $X = X_0$ 

$$\hat{Y}_0 \sim N \left( \beta_0 + \beta_1 X_0, \sigma \sqrt{\frac{1}{n} + \frac{(x_0 - \overline{x})^2}{\sum (x_i - \overline{x})^2}} \right)$$

$$\frac{(n-2)S_e^2}{\sigma^2} \sim \mathcal{X}_{n-2}^2$$

$$\implies EY_0 \in \hat{Y}_0 \pm t_{\frac{\alpha}{2}; n-2} \cdot S_e \sqrt{\frac{1}{n} + \frac{(x_0 - \overline{x})^2}{\sum (x_i - \overline{x})^2}}$$
